

METHOD AND APPARATUS FOR STORING MPEG-2 TRANSPORT STREAMS
5 USING A CONVENTIONAL DIGITAL VIDEO RECORDER

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a division of US Application No. 09/465,415, filed
10 December 16, 1999.

BACKGROUND OF THE INVENTION

The present invention relates to a digital video recorder and, more
15 particularly, to a method and apparatus for storing a compressed MPEG-2
transport data stream with a conventional digital video recorder.

A conventional digital video (DV) recorder records a digitized version
of an analog television signal. The analog signal may be the signal of the NTSC
(National Television Systems Committee) color television system of the United
20 States and Japan, the PAL (Phase Alteration Line Rate) television system of parts
of Europe, or the SECAM (Se'quentiel Couleur 'a Memoire) television system of
France, Russia and eastern Europe. For example, to digitally record the analog
television signal of the NTSC system, the separate luminance and chrominance
signals of the video signal are first sampled and quantized. Intraframe
25 compression is applied to the digital data representing the video signal using
techniques such as adaptive quantization (AQ), discrete cosine transformation
(DCT), and variable length coding (VLC). Following compression, error correction
is added to the data. The audio portion of the signal is processed in a similar
manner. The digital audio and video data are copied to data elements of a digital
30 video (DV) frame data structure and the audio and video data elements of the DV

frame structure are stored as separate segments of recording tracks on a magnetic tape.

The input and output of most DV recorders are by means of isochronous data transport as defined by the IEEE 1394-1995, STANDARD FOR
5 A HIGH PERFORMANCE SERIAL BUS, incorporated herein by reference. The IEEE 1394 standard defines a basic mechanism for real time data transport including an isochronous data packet 10, as illustrated in FIG. 1. However, the IEEE 1394 standard does not establish the protocols needed for specific application requirements such as sending DV data over the bus. The format of the
10 data structure for isochronous transmission of DV data across the IEEE 1394 serial bus is described in the International Standards Organization (ISO)/International Electrotechnical Commission (IEC) standards for DIGITAL INTERFACE FOR CONSUMER ELECTRONIC AUDIO/VIDEO EQUIPMENT, ISO/IEC 61883-1 and 61883-2, incorporated herein by reference. ISO/IEC 61883
15 defines the Common Isochronous Packet (CIP) format that is the basis of the 1394 DV data packet 30, illustrated in FIG. 2. The DV packet 30 comprises a CIP header 32 and a data field 34 of 480 bytes. For isochronous transmission on the IEEE 1394 bus, the DV data packet 30 is inserted into the data block of the IEEE 1394 isochronous data packet 10.

20 The IEEE 1394 bus sequences through three general phases: a cycle initiation phase, an isochronous phase, and an asynchronous phase. At the completion of the cycle initiation phase, transfer of isochronous data packets 10 is enabled. Devices connected to the bus having an allocated isochronous channel arbitrate for the bus. When a device gains access to the bus, it locates the start of
25 the DV video frame and buffers the next 250 valid data packets to collect a complete DV frame. The CIP headers are discarded and the remaining 120,000 bytes defines an NTSC DV frame.

A 525 lines, NTSC DV video frame 50 comprises odd and even video fields and is encoded into ten digital interface format (DIF) sequences 52, as illustrated
30 in FIG. 3. Each DIF sequence 54 comprises 150 DIF blocks 54 as illustrated in

FIGS. 3 and 4. The 150 DIF blocks comprise a header (H) section 70, a subcode (SC) section 72, a video auxiliary (VAUX) section 74, and an audio and video data section 75. The audio data section 76 (indicated by a bracket in FIG. 4) comprises nine (A_0 - A_8) audio DIF blocks. The video portion of the audio-video section 75
5 comprises 135 (V_0 - V_{134}) video DIF blocks 78 (indicated by a bracket in FIG. 4). Referring to FIG. 3 each DIF block 54 includes an ID section 56 and a data section 58.

Digital recording of analog television signals provides a number of advantages over analog recording of those signals. However, television is in
10 transition from an analog system to a digital system based on the MPEG-2 video compression standard. In the digital television (DTV) system, signals for each of the elements of a television program are digitized. The digital elementary data streams are compressed and then multiplexed into a single MPEG-2 transport data stream for transmission to a receiver. At the receiver, the transport stream is
15 separated into the constituent elementary data streams which are decompressed and presented to the viewer. MPEG-2 transport data streams can be recorded with a dedicated MPEG video recorder. However, purchasing a dedicated video recorder to record MPEG video, particularly during the transition to DTV, is an undesirable additional expense.

20 What is desired, therefore, is a method of storing an MPEG transport data stream on a conventional DV format video recorder for playback on a DTV receiver.

SUMMARY OF THE INVENTION

25 The present invention overcomes the aforementioned drawbacks of the prior art by providing a method of processing data comprising the steps of copying the data to a data block formatted for digital video, and storing the data block on a storage medium in a digital video storage format. For example, packetized MPEG-2 transport stream data can be stored on a conventional digital video (DV)
30 recorder by copying the transport stream data to one or more digital interface

format (DIF) data blocks that are part of a digital video (DV) frame data structure. The DV frames containing the transport stream data are then recorded on video tape. The DV frames can be input to the video recorder by insertion into isochronous data transfer packets for transfer over an IEEE 1394 bus. On the other hand, if the data is formatted according to MPEG or another data formatting standard supported by IEEE 1394, the data may be transferred to the recorder before being inserted into a DV frame for storage. To present the stored data, the data is extracted from the DV frames and then decoded and presented using the customary applicable methods.

10 An apparatus for storing data with a digital video recorder is also disclosed comprising an accumulation buffer to accumulate a predetermined quantity of the data and a frame packetizer to copy the data to a data block of a digital video frame.

15 The foregoing and other objectives, features and advantages of the invention will be more readily understood upon consideration of the following detailed description of the invention, taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

20 FIG. 1 is an illustration of the data structure of an IEEE 1394 isochronous data packet.

FIG. 2 is an illustration of the data structure of a digital video data packet to be inserted into the data block of the IEEE 1394 isochronous data packet of FIG. 1.

25 FIG. 3 is an illustration of the data structure of a digital video frame.

FIG. 4 is an illustration of the data structure of a digital interface format (DIF) sequence of the digital video frame of FIG. 3.

FIG. 5 is a block diagram of a digital television (DTV) system, including a digital video recorder.

FIG. 6 is an illustration of the structure of a digital interface format (DIF) block of a DV frame in which MPEG transport stream data is stored.

FIG. 7 is an illustration of an embodiment of a header for the MPEG transport stream data stored in a digital interface format (DIF) block of a DV frame as illustrated in FIG. 6.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring to FIG. 5, a digital television system comprises, generally, a transmitter or emission station 100 (indicated by a bracket), a transmission channel 102 (indicated by a bracket), a receiver 104 (indicated by a bracket), and a monitor 106. In the emission station 100, separate video 108, audio 110, and data 112 elementary data streams are appropriately encoded and compressed in video 114, audio 116, and data 118 encoders. The compressed elementary data streams are input to a program multiplexer 120 that combines the separate elementary data streams into a single transport data stream 122. The transport data stream 122 is transmitted to a receiver 104 over a transmission channel 102 such as a terrestrial or satellite broadcast system or a cable. At the receiver 104 which may be a set-top-box, the MPEG-2 transport data stream is separated into its constituent compressed video 124, audio 126, and data 128 elementary streams by a demultiplexer 130. The individual elementary data streams are decompressed and decoded in video 132, audio 134, and data 136 application decoders. The decompressed and decoded video 138, audio 140, and data 142 elementary streams are input to a presentation system 144 for presentation to the viewer, usually by display on the monitor 106.

The receiver 104 may be connected to a digital video (DV) format video recorder or camcorder 146 by a bus 148 conforming to the IEEE 1394-1995, STANDARD FOR A HIGH PERFORMANCE SERIAL BUS. In the present invention, the packetized MPEG-2 transport stream data 122 is inserted into a DV data packet by a frame packetizer 150. The DV frame is, in turn, inserted into an IEEE 1394 isochronous transfer data packet by an IEEE 1394 isochronous data

encoder 152 for transmission over the IEEE 1394 bus 148 to the video recorder 146. In the video recorder 146, the DV data packets are recovered from the transfer data packets by a depacketizer 153 and the DV formatted frames are stored on a storage medium 154, usually a DV formatted magnetic videotape. At
5 play time, the DV formatted data are inserted into an IEEE 1394 isochronous packet by an encoder 155 and transmitted over the bus 148 to the transmission channel 102 and to the receiver 104 where the MPEG data is extracted. The MPEG transport stream data are decoded by the application decoders 132, 134, and 136 for display by the presentation system 144.

10 The IEEE 1394 standard also provides a mechanism for transferring data in an MPEG format over the serial bus 148. As an alternative embodiment, the transport stream data 122 could be encoded in the IEEE 1394 encoder as MPEG formatted data encapsulated in an IEEE 1394 packet. At the recorder 146, the MPEG data would be extracted from the IEEE 1394 data packet in the
15 depacketizer 153. In this embodiment, the MPEG data would be inserted into the DV data format by a DV frame packetizer 157 in the recorder 146. The DV formatted data would then be stored on the storage medium 154. At play time, the DV formatted data would be copied from the storage medium 154 by the encoder 155. In the encoder 155, the MPEG data is extracted from the DV
20 formatted data packets and then the MPEG data is inserted into an IEEE 1394 data packet for transmission over the serial bus 148. In this alternative embodiment, the MPEG data would be recovered from the IEEE 1394 packet in the reconstruction depacketizer 159.

The IEEE 1394 high speed serial bus 148 provides for both asynchronous
25 and isochronous data transfer. Isochronous operation guarantees a bandwidth for devices, such as audio/video devices, that require constant data transfer rates. Isochronous transactions use a single isochronous data packet format to perform multicast or broadcast transfers to one or more nodes (attached devices) on the bus 148. The format of an IEEE 1394 isochronous data packet is illustrated in
30 FIG. 1. The packet comprises, generally, a header 12 and a data block 14. The

header 12 specifies the length of the data in the packet 16, an isochronous channel number 18 that identifies the nodes to which the isochronous transfer is to be directed, a transaction code 20, and a header cyclic redundancy check (CRC) 22. A cyclic redundancy check (CRC) 24 is also provided for the data block 14. The maximum data payload 26 (indicated by a bracket) of the isochronous data packet 10 varies with the data capacity of the specific IEEE 1394 serial bus. The maximum payload 26 of the smallest isochronous packet (for a 100 Mbit per sec. bus) is 1024 bytes. To transfer digital video format (DV) data over the serial bus, a DV data packet 30, as illustrated in FIG.2, is inserted into the data field of the IEEE 1394 isochronous data packet 10.

The structure of the DV data packet 30 is defined by ISO/IEC 61833-1 and 61833-2, DIGITAL INTERFACE FOR CONSUMER ELECTRONIC AUDIO/VIDEO EQUIPMENT, and is illustrated in FIG. 2. The DV data packet 30 comprises a CIP (Common Isochronous Packet) header 32 and a 480 byte data field 34. The CIP header 32 includes fields for source node identification (SID) 36, data block size (DBS) 38, function number (FN) 40, quadlet packing count (QPC) 42, source packet header (SPH) 44, format identification (FMT) 46, signal type (STYPE) 48, and a time stamp (SYT) 49 for synchronization of video frames.

The data of a DV frame 50 for NTSC television is divided into ten digital interface format (DIF) sequences 52 as illustrated in FIG. 3. A DV frame for PAL television comprises 12 DIF sequences. As illustrated in FIGS. 3 and 4, each DIF sequence 52 comprises 150 DIF blocks 54. A DIF sequence 52 includes a header section (DIF block H0) 70, a subcode section (DIF blocks SC0 and SC1) 72, a video auxiliary section (DIF blocks VA0-VA2) 74, and an audio-video section 75. The audio-video section 75 comprises an audio section (DIF blocks A0-A8) 76 (indicated by a bracket in FIG. 4), and a video section (DIF blocks V0-V134) 78 (indicated by a bracket in FIG. 4). Referring again to FIG. 3, each DIF block comprises a three byte identification (ID) 56 and a 77 byte data section 58. The DIF block ID 56 indicates the type of DIF block (for example, video), the subsequence number and the DIF block number (0 to 134).

In the present invention, MPEG-2 transport data stream packets are inserted into the last 76 bytes (the target data block) of the 77 byte data fields 58 of a plurality of video section DIF blocks 78 of one or more DV frames 50. Data is not stored in the first byte of the data field 58 because the DV recorder may alter the value of this byte as an error indicator. When writing to the recorder this byte is usually set to zero indicating no error, although other values are possible. DV frame packets 30, containing the DV formatted frames, are inserted into the payload of IEEE 1394 isochronous data transfer packets 10 for transfer over the IEEE 1394 bus. At the video recorder, the DV frames are extracted from the bus data stream and stored as DV formatted data on the videotape 154. Referring to FIG. 6, in an embodiment of the invention, the first six bytes of the target data field (the last 76 bytes of the data field 58) are used for MPEG header information 80 and the remaining 70 bytes are used to store the packetized MPEG-2 transport stream data 82. The MPEG header 80 is used by the decoder in extracting MPEG data from the DV frame structure 50 during playback. As illustrated in FIG. 7, the MPEG header comprises a length field 86 specifying the number of bytes of MPEG data in the DIF block starting from the MPEG ID byte 88 and ending at the last MPEG transport stream data byte of the DIF block 54. If a DIF block contains no MPEG data, the final four fields of the MPEG header 80 will contain no data and the length field 86 will be zero. The MPEG-2 ID field 88 contains a unique number that indicates that the data block of the DIF block contains MPEG-2 data. For example, the unique number might be the ASCII character "M" that has the value 77. The version field 90 contains a number indicating the version of the MPEG-2 standard and any MPEG-to-DV data storage specification applicable to the data in the block. On the other hand, the MPEG ID 88 and version 90 fields could be eliminated if the data is known to be MPEG-2 data or if the transport stream validity is checked by the MPEG decoder.

The redundancy field 92 of the DIF block contains an incrementing number indicating when new data is being stored in the DIF block. The DV format utilizes intraframe compression. The MPEG-2 compression process utilizes both

intraframe and interframe data compression. The inventors realized that the 22.68 Mbps data capacity of the DV tape may substantially exceed the data rate of the MPEG transport stream 122. For example, standard definition MPEG-2 video has a maximum data rate of six Mbps. When the data rate capacity of the tape exceeds the data rate of the MPEG transport stream, the MPEG data can be stored redundantly on the tape. At 30 frames per second, approximately 200,000 bits of MPEG data must be stored in each DV frame structure 50. However, each DV frame 50 has a data capacity of 756,000 bits and the extra capacity can be used to redundantly store the MPEG data in multiple DIF blocks. If a DIF block is lost in transmission or storage, the data can be recovered from an identical DIF block in another DIF sequence. Further, when operating in a trick play mode the IEEE 1394 data stream may contain only fragments of each DV frame. Depending on trick play speed and data redundancy, it may be possible to reconstruct the original MPEG-2 transport stream from fragments of the DV frames. The redundancy value is a function of the DV frame structure capacity (756,000 bits) and the MPEG-2 data rate and can be expressed as:

$$Redundancy = \text{floor} \left\lceil \frac{DVC_frame_capacity \cdot DVC_frame_rate}{MPEG2_bit_rate} \right\rceil$$

Referring to FIG. 5, to control the redundant storage of MPEG data, the receiver 104 accumulates 756,000 bits (one DV frame of data) in an accumulation buffer 158 as the MPEG transport stream data arrives at the receiver 104 from the emission station 100. When this quantity of data has been accumulated, it is placed in the data section of a DV frame 50. This data is repeatedly output to the frame packetizer 150 while the next 756,000 bits of data are received from the emission station 100 and accumulated. The DV packet 30 is sent to the video recorder 154 and the new accumulation of data is then placed in a new DV frame with a redundancy number incremented by one from that of the previous DV frame. The process is repeated until the entire MPEG transport stream is stored.

When the stored video is played, the data in the DV frames stored on the tape is sent from the recorder 154 to the receiver 104. The MPEG ID field 88 of MPEG header 80 (see FIG. 7) is used to identify the data in the DV frames as MPEG transport stream data. The offset field 94, see FIG.7, is used to reconstruct the MPEG-2 transport stream. The offset specifies the position of the MPEG data in the DIF block relative to the MPEG data from other DIF blocks of the current DV frame or in redundant frames. Preferably, the first DIF block of a DV frame has an offset of zero. If this DIF block contains 70 bytes of data, then the offset number of the next DIF block would be 70.

10 The transport stream is reconstructed by extracting the MPEG data from the IEEE 1394 packets in a reconstruction depacketizer 159 and then placing the MPEG-2 data from each of the DIF blocks 54 into a reconstruction buffer 156, illustrated in FIG. 5. The location of specific data in the reconstruction buffer 156 is the sum of the offset value 94 and a frame storage index equal to one byte past the last storage location used by the DVC frames having the previous redundancy value. The frame storage index is initially set to zero. If any DIF blocks are missing, redundant DIF blocks 54 from redundant DV frames can be placed into the reconstruction buffer 156. When a frame with a new redundancy value is received, the frame storage index is set to one byte past the last byte stored with the previous redundancy value 92. The MPEG data from the redundant frame is then stored at the location identified by the sum of the offset value 94 of the DIF block and the frame storage index. Data from each set of frames with a new redundancy value 92 is appended to the data in the reconstruction buffer 156. A discontinuity in the redundancy value would indicate that a new or discontinuous MPEG-2 transport stream is being received.

The method and apparatus of the present invention may be used to store data other than MPEG-2 transport stream data on DV tape. For example, files from a PC hard disk or other data that may or may not be related to stored MPEG transport stream data (such as web page uniform resource locators (URLs), recording time, or system information) could be stored on DV tape utilizing the

method. Further, if the data rate capacity of the DV tape exceeds the data rate of the MPEG transport stream, ancillary data can be stored by the DV recorder utilizing the method. Such ancillary data could include trick play frames to aid in trick play operation (such as, fast forward or reverse operation) of the video recorder. The trick play mode data may include MPEG frames stored redundantly on the tape to ensure that data is can be retrieved during fast play modes.
